2 Category Theory

2.1 Category

Definition 2.1 (Category) A **category** \mathcal{C} consists of a collection $ob(\mathcal{C})$ of **objects**, and $\forall A, B \in ob(\mathcal{C})$, there is a collection $\mathcal{C}(A, B)$ of **morphisms** from A to B . With following three axioms satisfied:

1. **Composition:** $\forall A, B, C \in ob(\mathcal{C})$, if $f \in \mathcal{C}(A, B)$ and $g \in \mathcal{C}(B, C)$, then there is a function $g \circ f \in \mathcal{C}(A, C)$ called composition of f and g .
2. **Associativity:** $(h \circ g) \circ f = h \circ (g \circ f)$, $\forall f \in \mathcal{C}(A, B)$, $g \in \mathcal{C}(B, C)$, $h \in \mathcal{C}(C, D)$.
3. **Identity laws:** $\forall A \in ob(\mathcal{C})$, $\exists 1_A \in \mathcal{C}(A, A)$, called the identity of A . And $\forall f \in \mathcal{C}(A, B)$, we have $f \circ 1_A = f = 1_B \circ f$.

Example 2.1 (Category of Sets: **Set**) For a category \mathcal{C} , where $ob(\mathcal{C})$ is a collection of sets, here we consider each set as one object, no matter the cardinality of it. Given two set A and $B \in ob(\mathcal{C})$, the mapping or morphism between two sets is exactly a function from A to B . Together with all the sets we have and the functions between each two sets we call them **Set**, the category of set.

Example 2.2 (Category of Groups and Rings: **Grp** and **Ring**) We have a collection of groups, and a morphism between every two given group G and H which is so-called group homomorphism. Then all these groups together with the group homomorphisms are called category **Grp** of groups. Similarly, there is a category **Ring** of rings and ring homomorphisms.

Example 2.3 (Category of Vector Spaces over field k : **Vect_k**) For a field k , **Vect_k** consists the vector fields over k and the mapping between two vector spaces H to W which will be the k linear transformations from H to W , i.e. $\mathcal{L}(H, W)$.

Example 2.4 (Category of Topological Spaces: **Top**) There is a collection of topological spaces and the mapping between topological spaces are continuous maps. Together the topological spaces and maps are called **Top**.

The 'Category' is not a unique object but a structure of mathematical objects. For instance, Group is something in a set satisfy associativity and there is an identity and inverse under specific operation, the set in definition of group can be anything, they could be functions, person, computer program, formula for Rubik's cube... So similarly, here the category of some mathematical object is not represent all these object in the collection. You can construct any category you want with few objects as long as you give the morphisms and they satisfy the axioms.

Take **Set** as example, the category of set not necessarily contain all sets, if you construct a category with limited number of sets, it still called **Set**.

Example 2.5 (Category of nothing: \emptyset) There is a collection of nothing and no morphisms between nothing, these called empty category \emptyset .

Example 2.6 (Category of one object: **1**) There is a category **1** with only one object in the collection and only Identity map.

Example 2.7 (Discrete Category) A category \mathcal{C} is discrete if $\forall A, B \in ob(\mathcal{C})$, $\mathcal{C}(A, B) = \emptyset$. This does not mean there is no mapping in \mathcal{C} , notice that $1_A \in \mathcal{C}(A, A)$, $\forall A$.

Example 2.8 (One object category constructed by a group) A group actually is a one object category. Differ this from category **1** that **1** has only identity but for group one element in it is a morphism. Let us put in a clear way. We have a group $G = \{e, g_1, g_2, \dots\}$, consider a category \mathcal{C} that $ob(\mathcal{C}) = G$, the identity morphism in $\mathcal{C}(G, G)$ is actually $e \in G$:

$$e(G) = e \cdot G = \{e \cdot e, e \cdot g_1, e \cdot g_2, \dots\} = \{e, g_1, g_2, \dots\} = G$$

and $\forall g \in G, g(G) \subseteq G$ from the closure of group structure, if $|G| < \infty$, then $g(G) = G, \forall g \in G$. The corresponding table below helps you to understand the isomorphism between mathematical structure.

Category \mathcal{C} with single object A	Group G
Maps in \mathcal{C}	Elements in G
\circ in \mathcal{C}	\cdot in G
$1_A \in \mathcal{C}(A, A)$	$e_G \in G$

We remark that the category of one mathematical object is a collection of some structural objects not necessarily all the objects, and we provide a example say one object category of group.

Now we put our focus into the morphisms in category, given A and B as object of category \mathcal{C} , the mapping in $\mathcal{C}(A, B)$ should not necessarily be so-called functions or transformations, we name the morphisms as transformations it is because for $f \in \mathcal{C}(A, B)$, we have $f(A) = B$, gives us feeling that the morphism f trans A into B .

We should consider it more abstract, the type of $f(A) = B$ is actually a one directional relation of A and B . If f is not some machine but a not comprehensive statement, for example: $f :=$ 'is bigger than', then $f(A) = B$ is a full statement:

$$f(A) = B \iff A \longrightarrow B \iff A \text{ is bigger than } B$$

Consider mapping as relation between different objects is one of core idea in category theory, it is a great abstraction and according to this we can find many isomorphism between different mathematical structures.

Definition 2.2 (opposite category) a category noted \mathcal{C}^{op} is said to be the opposite or dual category of given category \mathcal{C} , it has exactly the same object with all the arrows in \mathcal{C} reversed, that is:

$$ob(\mathcal{C}^{op}) = ob(\mathcal{C}) \text{ and } \mathcal{C}^{op}(B, A) = \mathcal{C}(A, B)$$

2.2 Functor

Definition 2.3 (Functor) We say a map of categories $\mathcal{F} : \mathcal{C} \longrightarrow \mathcal{D}$ is a functor, if it sends every A in $ob(\mathcal{C})$ to a $\mathcal{F}(A)$ in $ob(\mathcal{D})$ and a morphism $f : A \longrightarrow B$ of \mathcal{C} to a morphism $\mathcal{F}(f) : \mathcal{F}(A) \longrightarrow \mathcal{F}(B)$ of \mathcal{D} , while satisfies two axioms that

$$\mathcal{F}(id_A) = id_{\mathcal{F}(A)} \text{ and } \mathcal{F}(g \circ f) = \mathcal{F}(g) \circ \mathcal{F}(f)$$

where $A \in ob(\mathcal{C})$ and $f, g \in mor(\mathcal{C})$

The fundamental group map $\pi_1(*, *)$ can be considered as a functor from the category of topological space with the basepoint **Top*** to **Grp**. For any topological space X with a basepoint x specified, the functor send the pair $(X, x) \in ob(\mathbf{Top}^*)$ to its fundamental group $\pi_1(X, x) \in \mathbf{Grp}$, with give us the algebraic structure of the loops start at basepoint x in space X . In this case any $f \in \mathbf{Top}^*(X, Y)$ not

only a continuous map from X to Y but also a basepoint-preserving $f : (X, x) \rightarrow (Y, y)$, with its image under the functor $\pi_1(f) : \pi_1(X, x) \rightarrow \pi_1(Y, y)$.

For examples apart from algebraic topology, we have forgetful functors from **Grp** to **Set** which just by its name, the group forgets its structure under the operation but keep its members as a set. And free functors can be considered as dual functor of forgetful, send a set to a group with an operation and add more elements in the set to make it a group.

One type a functor is widely used in categorical language, for a locally small category \mathcal{C} and $A \in ob(\mathcal{C})$, we have $H^A = \text{Hom}(A, -) : \mathcal{C} \rightarrow \mathbf{Set}$. The morphism functor send every element X in the category to the morphism set $\text{Hom}(A, X)$, which is the set of all morphisms from A to X . And the morphism map under functor is $H^A(g) = \text{Hom}(A, g) : \text{Hom}(A, X) \rightarrow \text{Hom}(A, Y)$, simply by $f \mapsto g \circ f$ for all $f : X \rightarrow Y$.

But if the position of given $A \in ob(\mathcal{C})$ switch then everything changed. For similar morphism functor $H_A = \text{Hom}(-, A)$, the narrow preserving diagram make no sense, the image $H_A(g)$ cannot be defined for certain $g \in \text{Hom}(X, A)$, so the functor is actually defined on the opposite category of \mathcal{C} , that is, $H_A = \text{Hom}(-, A) : \mathcal{C}^{op} \rightarrow \mathbf{Set}$ (See diagram below). This gives us the motivation to define the special functor on the opposite category.

Definition 2.4 (contravariant functor) Let \mathcal{C} and \mathcal{D} be categories, a functor $\mathcal{C}^{op} \rightarrow \mathcal{D}$ is said to be the contravariant functor from \mathcal{C} to \mathcal{D} .

2.3 Natural transformations

We have defined the categories and functors as the mapping of two categories so far, the definition of functors is actually equivalent to say the diagram below commutes.

So it is so natural to define a new mapping to fill in the gaps in the dashed line at the base of the triangle. To be precise, we have to make the bottom rectangular commutes. Such mapping between two functors comes up in a natural way thus we call it natural transformations.

Definition 2.5 Given two categories \mathcal{C} and \mathcal{D} , and two functors $\mathcal{F}, \mathcal{G} : \mathcal{C} \rightarrow \mathcal{D}$, the natural transformation is a map of functors $\alpha : \mathcal{F} \rightarrow \mathcal{G}$, which consists a morphism $\alpha_X : \mathcal{F}(X) \rightarrow \mathcal{G}(X)$ for all $X \in \text{ob}(\mathcal{C})$ such that for all $f : X \rightarrow Y$, the following diagram commutes

$$\begin{array}{ccc} \mathcal{F}(X) & \xrightarrow{\mathcal{F}(f)} & \mathcal{F}(Y) \\ \downarrow \alpha_X & & \downarrow \alpha_Y \\ \mathcal{G}(X) & \xrightarrow{\mathcal{G}(f)} & \mathcal{G}(Y) \end{array}$$

2.4 Limits and colimits

Now we introduce two of the most important and powerful concepts in category theory. Limits and colimits give us a way to discover the mathematical structure universally and uniquely. Both of them are defined after a special functor.

Definition 2.6 (Category-shaped diagram) Let \mathcal{C} and \mathcal{D} be category and small category. The functor $\mathcal{F} : \mathcal{D} \rightarrow \mathcal{C}$ is a \mathcal{D} -shaped diagram in \mathcal{C} .

We have the category $\mathcal{D}[\mathcal{C}]$ called \mathcal{D} -shaped diagram category in \mathcal{C} where $\text{Hom}(\mathcal{F}, \mathcal{F}')$ are the natural transformations. And our limits will be defined in the image of one specific \mathcal{D} -shaped diagram in the category \mathcal{C} . We already know for any two $D, D' \in \mathcal{D}$, the image of \mathcal{F} make the rectangular commutes. Moreover, for fixed $A \in \mathcal{C}$, it should be commutative with every image of elements in \mathcal{D} under the functor.

Definition 2.7 (Cone) A cone on the \mathcal{D} -shaped diagram functor \mathcal{F} consists a vertex $A \in \text{ob}(\mathcal{C})$ and the family of maps in $\text{mor}(\mathcal{C})$ $f_i : A \rightarrow \mathcal{F}(D_i)$ where $i \in I$, $D_i \in \text{ob}(\mathcal{D})$, such that $\forall g_i : D_i \rightarrow D_{i+1}$ in \mathcal{D} , the cone diagram commutes:

We denote this cone as $(f_i : A \rightarrow \mathcal{F}(D_i))_{i \in I}$. Such cone-shaped structure is easy to find in any category and the number of such cones is large. So what we want to find is a so-called best cone which can be represented as the top cone of every cone and give us an universal structure of the category.

Definition 2.8 (Limits and colimits) The limits of \mathcal{F} is a vertex of the cone $(\varphi_i : \lim \mathcal{F} \rightarrow \mathcal{F}(D_i))_{i \in I}$ satisfying that for any cone of \mathcal{F} : $(f_i : A \rightarrow \mathcal{F}(D_i))_{i \in I}$, there is a unique map in $\text{mor}(\mathcal{C})$ $\tilde{f} : \lim \mathcal{F} \rightarrow A$ such that $\varphi_i \circ \tilde{f} = f_i$, $\forall i \in I$. The colimits is the dual of limits which is defined by reversing arrows. These are equivalent to say such diagram commutes for the simple case of any two $D_1, D_2 \in \text{ob}(\mathcal{D})$:

In categorical way, for one \mathcal{D} -shaped diagram functor \mathcal{F} , the image category \mathcal{C} can be considered as the category with objects are the vertex of cones defined on the functor \mathcal{F} , and $\lim \mathcal{F}$ is the terminal object while $\operatorname{colim} \mathcal{F}$ is the initial in such category.

3 The fundamental groupoid

3.1 Homotopy equivalence

For the category of topological space with basepoint \mathbf{Top}^* we mentioned before, its objects consists a pair (X, x) . The morphisms in \mathbf{Top}^* only continuously send space X to Y but also preserve the chosen basepoint x to y . In such case, the fundamental group is a functor $\pi_1(*, *) : \mathbf{Top}^* \rightarrow \mathbf{Grp}$, where \mathbf{Grp} is the category of groups with group homomorphisms. For a topological space take the homotopy class as the equivalence relation, a two path from x to y in space X should be considered as one if they in same homotopy class. But a path also can be considered as a morphism from x to y , we are saying in a categorical way, the morphism in category is equivalent to a path in topological space, that is:

$$\operatorname{Hom}_{\mathbf{Top}^*}(x, y) \sim \{\gamma \in C^0([0, 1], X) \mid \gamma(0) = x, \gamma(1) = y\}$$

Under this intuition, for any category \mathcal{C} , take all the morphisms as paths, we define the homotopy category $h\mathcal{C}$ as the category with the same objects as \mathcal{C} but with morphisms under the homotopy classes of maps.

Definition 3.1 (*Homotopy category*) For any category \mathcal{C} , the homotopy category $h\mathcal{C}$ is a category which

$$\operatorname{ob}(h\mathcal{C}) = \operatorname{ob}(\mathcal{C}) \quad \text{and} \quad \operatorname{mor}(h\mathcal{C}) = \operatorname{mor}(\mathcal{C}) / [\text{homotopy class}]$$

For the unbased topological space category \mathcal{U} , recall a homotopy equivalence of topological space $X, Y \in \operatorname{ob}(\mathcal{U})$ is equivalent to the existence of $f \in \operatorname{Hom}(X, Y)$ and $g \in \operatorname{Hom}(Y, X)$ such that $g \circ f \simeq \operatorname{id}_X$ and $f \circ g \simeq \operatorname{id}_Y$. That is actually saying a homotopy equivalence in \mathcal{U} is an isomorphism in $h\mathcal{U}$.

Proposition 3.1 A group isomorphism $f_* \in \operatorname{Hom}_{\mathbf{Grp}}(\pi_1(X, x), \pi_1(Y, f(x)))$ with independence of the choice of basepoint x is induced by the homotopy equivalence $f \in \operatorname{Hom}_{\mathcal{U}}(X, Y)$.

Proof Let \square

3.2 Fundamental groupoid

Now we introduce a new mathematical construction, the groupoid. The name groupoid is come from the algebraic structure group but more general. A group can consider as a one object category in the very first example in category, for a singleton $\{*\}$ we have all its automorphisms as a group, which means the category with single object $*$ a point and all the elements in group as the morphisms in category. Groupoid is defined similar to this but on more than one objects.

Definition 3.2 (*Groupoid*) A groupoid (G, \circ) is a category which every morphism is isomorphism.

It is not hard to see a group is a groupoid, but the reverse is not. More clearly for $A \in \operatorname{ob}(G)$ where $G \in \mathbf{GP}$ we have $\operatorname{Hom}_G(A, A) = \operatorname{Aut}(A)$ is a group and a one object category. One fact is obvious that the category \mathbf{GP} is a category of categories, so every morphism is a functor.

Recall the definition of fundamental group, which is strictly dependent on the choice of base point x_0 . Somehow we know for a path-connected space X we have $\pi_1(X, x_0) \cong \pi_1(X, y_0)$, but this is according to the choice of the path from x_0 to y_0 , thus we still cannot say 'the fundamental group of X ' but 'the fundamental group of X on the point x_0 '.

This comes out as the motivation to define a new fundamental structure on the generalization of groups.

Definition 3.3 (*Fundamental groupoid*) For a topological space X and $x, y \in X$. We have $\text{Path}(x, y) := \{\gamma \in C^0([0, 1], X) \mid \gamma(0) = x, \gamma(1) = y\}$. The Fundamental groupoid of a topological space X is a category $\Pi(X)$ where $\text{ob}(X) = X$, and $\text{Hom}(x, y) = \text{Path}(x, y) / \sim$, where \sim is the equivalence relation under homotopy class respect to the chosen two points.

You should verify it quickly and easily that

$$\text{Hom}_{\Pi(X)}(x_0, x_0) = \pi_1(X, x_0)$$

The construction of fundamental groupoid will give us convenient way to study the structure of a topological space. Any continuous map $f : X \rightarrow Y$ induces a group homomorphism $f_* : \pi_1(X, x_0) \rightarrow \pi_1(Y, f(x_0))$ while we have to pick $f(x_0)$ properly. However the advantages of groupoids gives us a induced functor $\Pi(f) : \Pi(X) \rightarrow \Pi(Y)$ and this is more clean and formal. The diagram below show the difference between fundamental groups and fundamental groupoids. Both π_1 and Π are functors but groupoid induces functor (It is ok that you may think $\pi_1(f)$ is also a functor because group is one object category, but this brings us nothing new to describe the structure of space and we still have the hindrence to find the basepoint).

\mathbf{Top}^*	\mathbf{Grp}	$\{*\} \in \text{ob}_{\mathbf{Top}^*}$	\mathbf{Top}^*	\mathbf{GP}
X $\downarrow f$ Y	$\pi_1(X, x_0)$ $\downarrow \pi_1(f)$ $\pi_1(Y, f_0)$	x $\downarrow f$ $f(y)$	X $\downarrow f$ Y	$\Pi(X)$ $\downarrow \Pi(f)$ $\Pi(Y)$
$\xrightarrow{\pi_1}$	$\xrightarrow{\pi_1}$	$\xleftarrow{\pi_1}$	$\xrightarrow{\Pi}$	$\xrightarrow{\Pi}$

4 A generalization for van Kampen Theorem

4.1 Formal van Kampen Theorem

So far we know some fundamental groups of simple topological space. The idea is that we shall consider different topological space are constructed by those simple objects and figure out a formula to compute those fundamental group from what we already know.

Before we get into the theorem, let us first image what the fundamental group of space X will be if it can be decomposed into two open sets both path-connected and contain the basepoint. Take the shape ∞ as example it can be decomposed into the union of two S^1 and the basepoint is the intersection of two S^1 s. At first guess $\pi_1(\infty)$ somehow should be the product group $\mathbb{Z} \times \mathbb{Z}$ or the direct sum $\mathbb{Z} \oplus \mathbb{Z}$. But both of these is commutative, contradicts to the fact that once you get into a S^1 from basepoint you must finish the loop before you get into the other S^1 . In mathematical words, if a^2ba represents go twice counter-clockwise in left S^1 then go right S^1 and left again, this path should be distinct and never be the same as a^3b .

So in general, given a collection of open sets A_α which our topological space X can be decomposed to, we wish to construct a single group containing all $\pi_1(A_\alpha)$ as subgroups with non-commutative structure. That introduce the free product of groups.

Definition 4.1 (*categorical free product of groups*) Let $(G_i)_{i \in I}$ be a family of groups. The free product $*_{i \in I} G_i$ is a group satisfying the universal property:

\exists homomorphisms $\iota_j : G_j \rightarrow *_{i \in I} G_i$, s.t.

For any group H and any family of homomorphisms $f_j : G_j \rightarrow H$,

$\exists!$ homomorphism $\phi : *_{i \in I} G_i \rightarrow H$ making the diagram commute $\forall j \in I$

$$\begin{array}{ccc}
G_j & \xrightarrow{\iota_j} & *_{i \in I} G_i \\
& \searrow f_j & \swarrow \phi \\
& H &
\end{array}$$

The definition is under categorical language and it may be abstract. For a formal definition we have to construct the free product of any family of groups by defining the 'words' in the product. Here is an example for an equivalent constructive definition

Definition 4.2 (formal free product of groups) For a family of groups $(G_i)_{i \in I}$, a word is a finite sequence $s_1 s_2 \dots s_n$, where $s_k \in G_i \setminus \{e\}$ for some $i \in I$. A word is said be reduced if any two adjacent letters $s_i s_{i+1}$ belong to different groups. The free product $*_{i \in I} G_i$ is the group that elements are reduced words concatenated by the following reduction rules:

- i). If adjacent letters belong different groups, simply concatenate.
- ii). If adjacent $s_i s_{i+1}$ from the same group G_i , replace them with the result of their product $s_i \circ s_{i+1} \in G_i$ where \circ is the operation for specific G_i .
- iii). Remove the product if $s_i \circ s_{i+1} = e_i \in G_i$.

The two definitions are exactly the same but with different mathematical language. All is trying to say the free product group is also a group and it contains all the elements of the groups in our family. It allows us to represent the fundamental group by decomposed the space into many open pieces and remain the non-commutative structure.

Theorem 4.1 (van Kampen) If X is decomposed as the union of path-connected open sets A_α , with each containing the basepoint $x_0 \in X$ and $A_{\alpha_i} \cap A_{\alpha_j}$ is path-connected for any two, then the homomorphism $\phi : *_{\alpha} \pi_1(A_\alpha) \longrightarrow \pi_1(X)$ is surjective.

4.2 Categorical van Kampen theorem

One of our purpose is to introduce homotopy theory from categorical language, a potential way to do that is to find the equivalence between different mathematical description to same topological object or theorem. The van Kampen theorem is a good example.

Let $\mathcal{O} = \{U_i\}_{i \in I}$ be a cover of the space X where every U_i is path connected open subsets and $\bigcap_{i \in K} U_i \in \mathcal{O}$, where $K \subseteq I$ and $|K| < \infty$, which means the intersection of finitely many subsets in \mathcal{O} is again in \mathcal{O} . \mathcal{O} can be considered as a category with objects are those open subsets and morphisms are the inclusions between sets. In such way the fundamental groupoid functor restricted to the space and maps in \mathcal{O} sends us to the category of groupoid, that is, $\prod|_{\mathcal{O}} : \mathcal{O} \longrightarrow \mathbf{GP}$. And what van Kampen theorem says in most general categorical words is the fundamental groupoid is the initial objects in the category of all vertex of cones on the groupoid functor.

Theorem 4.2 (General van Kampen) The groupoid $\prod(X)$ is the colimit of \mathcal{O} -shaped diagram in \mathbf{GP} , in mathematical words:

$$\prod(X) \cong \text{colim}_{U_i \in \mathcal{O}} \prod(U_i)$$

Proof To construct a proper proof, we have to verify the universal property of colimits. Fundamental groupoid functor restricted on the cover is a map between two categories $\mathcal{O} \longrightarrow \mathbf{GP}$, which is a \mathcal{O} -shaped diagram. The theorem is saying $\prod(X)$ is $\text{colim}(\prod|_{\mathcal{O}})$. We have to show, $\forall G \in \mathbf{GP}$ and the family of $\phi_i : \prod(U_i) \longrightarrow G$, $\exists ! \Phi : \prod(X) \longrightarrow G$ such that $\phi_i = \Phi \circ \iota_i$ for every i , where ι_i is the morphism induced by the inclusions of subsets in category \mathcal{O} under functor $\prod|_{\mathcal{O}}$.

$$\begin{array}{ccc}
\Pi(U_1) & \xrightarrow{\Pi(\hookrightarrow)} & \Pi(U_2) \\
& \searrow \iota_1 & \swarrow \iota_2 \\
& \text{colim } \Pi|_{\mathcal{O}} = \Pi(X) & \\
& \swarrow \phi_1 & \searrow \phi_2 \\
& \downarrow \exists! \Phi & \\
& G &
\end{array}$$

Our proof includes two steps. First we have to define the morphism $\Phi : \Pi(X) \rightarrow G$ then show it is unique. Be careful that we are working in the category of groupoid, which means any morphism between two objects is a functor, thus our map should both consider the image of objects and morphisms. $\text{ob } \Pi(X)$ is points of X , $\forall x \in X$, $\exists U_i \in \mathcal{O}$ s.t. $x \in U_i$. So it is natural to define

$$\Phi_{\text{ob}}(x) := \phi_i(x), \text{ for } x \in U_i$$

It is well-defined by the closed of intersection in \mathcal{O} . For $x \in U_i \cap U_j$, we have two inclusions $\iota_i : U_i \hookrightarrow U_i \cap U_j$ and $\iota_j : U_j \hookrightarrow U_i \cap U_j$ implies $\phi_i(x) = \phi_{i \cap j}(x) = \phi_j(x)$, so it is independent of the choice of U_i .

The morphism map is somehow similar, notice that $\text{mor}(\Pi(X))$ are the homotopy class $[f] : x \rightarrow y$ of the path. As $f([0, 1])$ is compact and \mathcal{O} covers X , by Lebesgue's Covering Lemma we have a subdivision $0 = t_0 < t_1 < \dots < t_n = 1$ and $\{U_{i_1}, U_{i_2}, \dots, U_{i_n}\} \subseteq \mathcal{O}$ such that $f([t_{k-1}, t_k]) \subset U_{i_k}$. We get a homotopy subclass on U_{i_k} by restricting our f on the interval $[t_{k-1}, t_k]$ and we get f_k such that $[f] = *_{k=1}^n [f_k]$ where f_k is a path in U_{i_k} from x_{k-1} to x_k . After those set up we can define the morphism map of our $\Phi : \Pi(X) \rightarrow G$

$$\Phi_{\text{mor}}[f] := \phi_{i_n}([f_n]) \circ \phi_{i_{n-1}}([f_{n-1}]) \circ \dots \circ \phi_{i_2}([f_2]) \circ \phi_{i_1}([f_1])$$

It is independent of the choice of U_i again by the closed intersection of our cover thus it is well-defined. Now we can verify the universal property of the given functor which is the uniqueness of given Φ . Suppose there is another functor $\Psi : \Pi(X) \rightarrow G$ such that $\phi_i = \Psi \circ \iota_i$ for every i .

Consider any $x \in X$, there is $x \in U_i$ for some $U_i \in \mathcal{O}$ which gives the induced inclusion map $\iota_i(x) = x$. So

$$\Psi(x) = \Psi(\iota_i(x)) = \phi_i(x) = \Phi(x)$$

which says the two functor have same image on $\text{ob}(\Pi(X))$. For any $[f] \in \text{Hom}_{\Pi(X)}(x, y)$, we have the same subdivision $[f] = *_{k=1}^n [f_k]$, thus $\Psi([f]) = \Psi([f_1] * [f_2] * \dots * [f_n]) = \Psi([f_n]) \circ \dots \circ \Psi([f_2]) \circ \Psi([f_1])$. Notice that $[f_k]$ in $\text{Hom}_{\Pi(U_{i_k})}$ so it is the same after applying the functor induced by the inclusion map, that is $[f_k] = \iota_{i_k}([f_k]) \in \text{Hom}_{\Pi(X)}$. In conclusion we have

$$\begin{aligned}
\Psi([f]) &= \Psi([f_n]) \circ \dots \circ \Psi([f_2]) \circ \Psi([f_1]) \\
&= \Psi(\iota_{i_n}[f_n]) \circ \dots \circ \Psi(\iota_{i_2}[f_2]) \circ \Psi(\iota_{i_1}[f_1]) \\
&= \phi_{i_n}([f_n]) \circ \dots \circ \phi_{i_2}([f_2]) \circ \phi_{i_1}([f_1])
\end{aligned}$$

which is exactly $\Phi([f])$. Thus the universal property is verified. \square

The detail proof above is not hard to understand, the key to verify the universal property for categorical objects is to construct a proper one based on what we already have. For those categorical expert one should really easy to follow the proof just by understand four equations of the definitions and

verifications. The diagram below review our proof and picture what we are working on so far.

Proof by verifying the universal property is not hard but our proof is somehow different because our working is in the category of groupoid **GP**. Every groupoid is a category so the morphism between any two is a functor, which means we have to verify the image both on objects and morphisms in specific groupoid. If we move to the fundamental group version of van Kampen then will be more trivial.

Theorem 4.3 (Categorical van Kampen) *The group $\pi_1(X, x)$ is the colimit of the \mathcal{O} -shaped diagram restricted on the cover $\pi_1|_{\mathcal{O}} : \mathcal{O} \rightarrow \mathbf{Grp}$, in mathematical words:*

$$\pi_1(X, x) \cong \text{colim}_{U_i \in \mathcal{O}} \pi_1(U_i, x)$$

Proof (Categorical functor proof) The proof follows formally from our previous one but there is some details we need to talk about. Our goal is the same that to verify the universal property, but this time we focus on the category of group **Grp**. Recall we consider group as special groupoid with a single object and the elements of group as the morphisms. We consider the localize functor:

$$\begin{aligned} B_{x_0} : \mathbf{GP} &\longrightarrow \mathbf{Grp} \\ \forall G \in \text{ob}(\mathbf{GP}), B_{x_0}(G) &= \text{Hom}_G(x_0, x_0) \\ \forall \mathcal{F} \in \text{Hom}_{\mathbf{GP}}(G, H), B_{x_0}(\mathcal{F}) &= \mathcal{F}|_{\text{Hom}_G(x_0, x_0)} \end{aligned}$$

The definition for this functor on morphism is a restriction of \mathcal{F} on the groupoid G which itself a category, that is, $\mathcal{F}|_{\text{Hom}_G(x_0, x_0)} : \text{Hom}_G(x_0, x_0) \rightarrow \text{Hom}_H(\mathcal{F}(x_0), \mathcal{F}(x_0))$. By this functor for any elements in our \mathcal{O} -shaped diagram, we have $B_{x_0}(\prod(U_i)) = \text{Hom}_{\prod(U_i)}(x_0, x_0) = \pi_1(U_i, x_0)$, the same to $\prod(X)$. We have a bridge from **GP** and reconsider the last proof, the diagram below commutes

$$\begin{array}{ccccc} \mathcal{O} & \xrightarrow{\quad \Pi \quad} & \mathbf{GP} & \xrightarrow{B_{x_0}} & \mathbf{Grp} \\ \\ U_i & \xrightarrow{\quad \Pi(*) \quad} & \prod(U_i) & \xrightarrow{B_{x_0}(*)} & \pi_1(U_i, x_0) \\ \downarrow \iota & & \downarrow \Pi(\iota) & & \downarrow B_{x_0}(\Pi(\iota)) \\ U_j & \xrightarrow{\quad \Pi(*) \quad} & \prod(U_j) & \xrightarrow{B_{x_0}(*)} & \pi_1(U_j, x_0) \end{array}$$

In last proof we show $\prod(X) \cong \text{colim}_{U_i \in \mathcal{O}} \prod(U_i)$ in **GP**, now if our functor B_{x_0} preserves the colimits in **GP** then it is done. In mathematical, we want to show

$$G = B_{x_0}(\text{colim}_{U_i \in \mathcal{O}} \prod(U_i)) \cong \text{colim}_{U_i \in \mathcal{O}} B_{x_0}(\prod(U_i)) = H$$

where $B_{x_0}(\text{colim}_{U_i \in \mathcal{O}} \prod(U_i)) = \pi_1(X, x_0)$ and $\text{colim}_{U_i \in \mathcal{O}} B_{x_0}(\prod(U_i)) = \text{colim}_{U_i \in \mathcal{O}} \pi_1(X, x_0)$, for convenience we use G and H to represent those two groups. Consider the mapping $\theta : H \rightarrow G$, for any element in H is a loop $[\gamma] \in U_i$ for some $U_i \in \mathcal{O}$. By the inclusion functor J_i from \mathbf{Grp} to \mathbf{GP} , $J_i([\gamma]) \in \text{Hom}_{\prod(U_i)}(x_0, x_0)$, then send to \square

Proof (Categorical equivalence proof) Now we give another proof totally based on the power of category. For \mathbf{Gp} and \mathbf{Grp} there are always two natural functors. One is the inclusion of categories $\mathcal{J} : \pi_1(X, x) \rightarrow \prod(X)$, which sends a group as one single object $*$ to a specific basepoint x , and sends the homotopy class of loops $[\gamma] \in \text{Hom}_{\pi_1(X, x)}(*, *)$ to the automorphism of x in $\prod(X)$. As a dual there is a contract functor $\mathcal{F} : \prod(X) \rightarrow \pi_1(X, x)$ with a set up that $\forall y \in X$ there exists a chosen path $\alpha_y : x \rightarrow y$ such that $\alpha_x = c_x$ is constant path, *i.e.* $f(t) = x, \forall t \in [0, 1]$. Moreover, for $y \in U_i$ for some $U_i \in \mathcal{O}$ lies entirely in U_i . These two functors are called categorical equivalence functors and each of them is the inverse equivalence to the other, which one should easy to verify $\mathcal{F} \circ \mathcal{J} = \text{Id}_{\mathbf{Grp}}$.

We shall assume our cover \mathcal{O} is finite and then general to infinite case. And the idea of proof is simple as the commutative diagram shows below, which we use \mathcal{F} and \mathcal{J} to build up a bridge between two colimits.

For any $y \in U_i$ by our set up to pick path $x \rightarrow y$ entirely in U_i , thus the functors travels three categories

$$\prod(U_i) \xrightarrow{\mathcal{F}_{U_i}} \pi_1(U_i, x_0) \xrightarrow{\psi_i} G$$

is an \mathcal{O} -shaped diagram $\psi_i \circ \mathcal{F}_{U_i} : \prod|\mathcal{O} \rightarrow \mathbf{GP}$, notice that a group could also be considered as groupoid. By the groupoid version of van Kampen, there exists a unique map in category of \mathbf{GP} that $\Phi : \prod(X) \rightarrow G$ such that $\psi_i \circ \mathcal{F}_{U_i} = \Phi \circ \iota_i$ for all i . By the uniqueness of Φ and the bridge $\mathcal{J} : \pi_1(X, x_0) \rightarrow \prod(X)$, we have a unique homomorphism $\Psi = \Phi \circ \mathcal{J}$ as required, which satisfies the universal property of colimits that $\Psi \circ i_i = \psi_i$, where i_i is the inclusion from $\pi_1(U_i, x_0)$ to $\pi_1(X, x_0)$ induced by the inclusion as sets, and ψ_i is the map $\pi_1(U_i, x_0)$ to G similar to ϕ_i before in \mathbf{GP} .

Our work is not done yet, we have to generalize to infinite case. For an infinite cover \mathcal{O} we have \mathcal{F} as the set of those finite subsets in \mathcal{O} which are closed under finite intersection. For a specific subset $S \in \mathcal{F}$, we denote the union of $U_i \in S$ as U_S and it is clear that S is a cover of U_S . Moreover, the \mathcal{F} is again a finite cover and can be considered as a category of \mathcal{O} in finite case, so we have

$$\begin{aligned} \text{colim}_{U_i \in S} \pi_1(U_i, x_0) &\cong \pi_1(U_S, x_0) \\ \text{colim}_{S_i \in \mathcal{F}} \pi_1(U_{S_i}, x_0) &\cong \pi_1(X, x_0) \end{aligned}$$

Now for any infinite cover \mathcal{O} we subdivide to \mathcal{F} and by argument before any loops in X has image in

some U_S , so all we need to prove is

$$\operatorname{colim}_{U_i \in \mathcal{O}} \pi_1(U_i, x_0) \cong \operatorname{colim}_{S_i \in \mathcal{F}} \pi_1(U_{S_i}, x_0) \cong \operatorname{colim}_{S \in \mathcal{F}} \operatorname{colim}_{U_i \in S} \pi_1(U_i, x_0)$$

The iterated colim is isomorphic to the single colimit $\operatorname{colim}_{(U_i, S_i) \in (\mathcal{O}, \mathcal{F})} \pi_1(U_i, x_0)$. The category $(\mathcal{O}, \mathcal{F})$ has morphism $(U_1, S_1) \rightarrow (U_2, S_2)$ if both $U_1 \subset U_2$ and $U_{S_1} \subset U_{S_2}$. So there is a natural inclusion functor that $\mathcal{I} : \mathcal{O} \rightarrow (\mathcal{O}, \mathcal{F})$ where the diagram below commutes

$$\begin{array}{ccc} U_1 & \xrightarrow{\mathcal{I}} & (U_1, \{U_1\}) \\ \downarrow & & \downarrow \\ U_2 & \xrightarrow{\mathcal{I}} & (U_2, \{U_2\}) \end{array} \quad \begin{array}{c} \mathcal{O} \qquad \qquad \qquad (\mathcal{O}, \mathcal{F}) \end{array}$$

where \mathcal{I} sends U_i to its singleton set $\{U_i\}$ in \mathcal{F} . One should easily verify the only difference between \mathcal{O} and $(\mathcal{O}, \mathcal{F})$ is that for a homomorphisms $\pi_1(U_1, x_0) \rightarrow \pi_1(U_2, x_0)$, it only applies in \mathcal{O} once but many times in $(\mathcal{O}, \mathcal{F})$ with the same result comes out, there is no new contribution to our colimit. On the other side is more trivial, by projection gives us the function $\mathcal{P} : (\mathcal{O}, \mathcal{F}) \rightarrow \mathcal{O}$. Those functors composite with $\pi_1 : \mathcal{O} \rightarrow \mathbf{Grp}$ gives us the isomorphism

$$\operatorname{colim}_{U_i \in \mathcal{O}} \pi_1(U_i, x_0) \cong \operatorname{colim}_{(U_i, S_i) \in (\mathcal{O}, \mathcal{F})} \pi_1(U_i, x_0)$$

$$\begin{array}{ccccc} & \pi_1(U_1, x_0) & & \pi_1(U_1, \{U_1\}) & \\ & \swarrow \iota_1 & \nwarrow \pi_1 & \swarrow \pi_1 & \searrow (\iota_1, I_1) \\ & \downarrow & U_1 \xrightleftharpoons[\mathcal{P}]{\mathcal{I}} (U_1, \{U_1\}) & \downarrow & \\ \operatorname{colim}_{U_i \in \mathcal{O}} \pi_1(U_i, x_0) & \xleftarrow{\quad} & & \xrightarrow{\quad} & \operatorname{colim}_{(U_i, S_i) \in (\mathcal{O}, \mathcal{F})} \pi_1(U_i, x_0) \\ & \swarrow \iota_2 & \nwarrow \pi_1 & \swarrow \pi_1 & \searrow (\iota_2, I_2) \\ & \downarrow & U_2 \xrightleftharpoons[\mathcal{P}]{\mathcal{I}} (U_2, \{U_2\}) & \downarrow & \\ & \pi_1(U_2, x_0) & & \pi_1(U_2, \{U_2\}) & \end{array}$$

The commutative diagram shows clearly how two easy functors between \mathcal{O} and $(\mathcal{O}, \mathcal{F})$ build up the isomorphism. And our prove end up with

$$\operatorname{colim}_{U_i \in \mathcal{O}} \pi_1(U_i, x_0) \cong \operatorname{colim}_{(U_i, S_i) \in (\mathcal{O}, \mathcal{F})} \pi_1(U_i, x_0) \cong \operatorname{colim}_{S_i \in \mathcal{F}} \pi_1(U_{S_i}, x_0) \cong \pi_1(X, x_0) \quad \square$$

What's so intersting is that to be reversed, recall that $\mathcal{F} : \prod(X) \rightarrow \pi_1(X, x_0)$. If we have uniquely $\Psi : \pi_1(X, x_0) \rightarrow G$ restricts to ψ_i on each $\pi_1(U_i, x_0)$, then $\Psi \circ \mathcal{F} : \prod(X) \rightarrow G$ restricts to $\psi_i \circ \mathcal{F}_{U_i}$ which is exactly ϕ_i , meaning it is the way to prove groupoid version if we can prove group version constructively, the van Kampen in groupoid and groups are equivalent.

4.3 Cofibrations

For a inclusion $i : A \hookrightarrow X$ of spaces, we say it has the homotopy extension property for a space Y if every homotopy $H : A \times [0, 1] \rightarrow Y$ and for every map $f : X \rightarrow Y$ with $f(i(a)) = H(a, 0)$ for every $a \in A$, there is a homotopy $\hat{H} : X \times [0, 1] \rightarrow Y$ such that $\hat{H}(i(a), t) = H(a, t)$ and $\hat{H}(x, 0) = f(x)$ for all $a \in A, x \in X, t \in [0, 1]$

Definition 4.3 (HEP) An inclusion $i : A \hookrightarrow X$ has a homotopy extension property if for any space Y , i has the left lifting property which makes the diagram commutes

$$\begin{array}{ccc} A & \xrightarrow{H} & Y^{[0,1]} \\ \downarrow i & \nearrow \exists \tilde{H} & \downarrow \text{ev}_0 \\ X & \xrightarrow{f} & Y \end{array}$$

5 Covering Space

5.1 Covering Space

We have already talked about the fundamental group and fundamental groupoid for topological space, then comes up with van Kampen theorem to calculate the fundamental structure for some nontrivial space. What we more focus on is the equivalent description to van Kampen theorem, show us the power of categorical language also give us some intuition to homotopy theory.

Now we come to covering space, recall how we prove $\pi_1(S^1) = \mathbb{Z}$ by covering the real line \mathbb{R} circle by circle to S^1 . But covering space is more than that to compute fundamental group. Unlike any other textbook, we will see covering space in categorical language and in homotopic way.

Definition 5.1 (Evenly Covering Space) An evenly covering space for space X consists a pair (\hat{X}, p) such that $p : \hat{X} \rightarrow X$ is surjective and $\forall x \in X$, there is an open neighborhood U_x where

$$p^{-1}(U_x) = \bigsqcup_{i \in I} V_i$$

for some disjoint open set V_i in \hat{X} , and $p|_{V_i} : V_i \rightarrow U_x$ is homeomorphism for every $i \in I$. We call $\{V_i\}$ is the sheets of \hat{X} over X and $F_x = p^{-1}(x) \in \bigsqcup_{i \in I} V_i$ is a fiber of the covering p .

It should be mentioned that the difference between evenly covering space and covering space is that the preimage of any neighborhood can be written as disjoint union or not. But in Algebraic Topological the covering we describe are almost all evenly, so in later words we consider cover is an evenly cover. One should verify any homomorphism is a cover. Most classical example is the covering we used to show $\pi_1(S^1) = \mathbb{Z}$ by $p : \mathbb{R} \rightarrow S^1$. We will see the strong connection between covering space and the fundamental groupoid or group, the following theorem describes how p acts on the space.

Theorem 5.1 (Unique path lifting theorem) For a cover $p : \hat{X} \rightarrow X$ with $e_0 \in F_{x_0}$ where $x_0 \in X$, we have

$$\begin{aligned} \forall f \in \{f \text{ a path} : I \rightarrow X | f(0) = x_0\}, \\ \exists! g \in \{g \text{ a path} : I \rightarrow \hat{X} | g(0) = e_0\} \end{aligned}$$

such that $p \circ g = f$

Proof For a evenly covered base space X , if f lies entirely on the sheet $S_{x_0} = \{V_i\}$ with respect to U_{x_0} , then $g = q \circ f$ where q is the homomorphic inverse of p such that $q|_{V_i} \circ p|_{V_i} = \text{id}|_{V_i}$, $\forall V_i \in S_{x_0}$, and the uniqueness comes from the unique inverse for homeomorphism. For a general case, by Lebesgue's Covering Lemma I is compact that we can partition I by $0 = t_0 < t_1 < \dots < t_n = 1$ according to the covering, making f maps every closed $[t_i, t_{i+1}]$ to an evenly covered neighborhood of $f(t_i)$, then by the evenly cover case and induction we can obtain the unique lifting. \square

What the unique path lifting theorem means is that for the cover $p : \hat{X} \rightarrow X$, any fundamental points x_0 in based space X lifted into the fiber F_{x_0} , and $\forall e_i \in F_{x_0}$. This theorem give us the intuition that the lifting also act on the homotopic calss of each path.

Corollary 5.1 *For a covering $p : \hat{X} \rightarrow X$ and a homotopy in X that $h : f \simeq f'$ start from x_0 lifts uniquely to a homotopy $H : g \simeq g'$ in \hat{X} start from e_0 .*

Proof For the homotopy $h : I \times I \rightarrow X$, by Lebesgue's Covering Lemma we can subdivide the compact $I \times I$ into many subsquares each of which maps to a fundamental neighborhood of f , by **Theorem 5.1** we see any paths in the homotopic class lifts to a unique path that h lifts uniquely to a homotopy $H : I \times I \rightarrow \hat{X}$ where f and f' lift to g and g' with $H : g \simeq g'$ that $H(0,0) = e_0$, and one should be easily verified that $h = p \circ H$. \square

Proposition 5.1 *The induced group homomorphism $p_* : \pi_1(\hat{X}, e_i) \rightarrow \pi_1(X, x_0)$ is a monomorphism, for all $e_i \in F_{x_0}$.*

Before discussing the algebraic structure of covering space, we first define two important covering space according to special group structures.

Definition 5.2 *Consider the covering $p : \hat{X} \rightarrow X$. We say p is regular if $\pi_1(X, x_0)/p_*(\pi_1(\hat{X}, e_i))$ is still a group, p is universal if $\pi_1(X, x_0)/p_*(\pi_1(\hat{X}, e_i)) = \pi_1(X, x_0)$ and it is the normal subgroup of \mathbb{Z} so it's regular.*

Example 5.1 *Any integer multiple winding of S^1 is a normal cover, say if a covering wrap the S^1 three times it is easy to calculate $p_*(\hat{X}, e_i) = 3\mathbb{Z}$. Moreover, the covering $p : \mathbb{R} \rightarrow S^1$ is universal because \mathbb{R} is simply connected that $\pi_1(\mathbb{R}, e_i) = 0$, we also call \mathbb{R} is the universal cover of S^1 .*

The relationship between covering space \hat{X} and based space X is defined on the structure of the underlying fundamental groups. But we want to study the structure more specifically, says we should generalize the idea of covering from topological space to any algebraic objects. One way to do this is to define the covering space on categories. Once we have the categorical covering, the induced homomorphism p_* will become a covering contain more information rather than a mapping. The way to generalize the covering space is working on the category called morphism category.

Definition 5.3 (Morphisms Category) *Let \mathcal{C} be any category and a $x \in \text{ob}(\mathcal{C})$, the morphism category of \mathcal{C} under x is a category $x \backslash \mathcal{C}$ such that*

$$\text{Ob}(x \backslash \mathcal{C}) := \bigcup_{y_i \in \text{Ob}(\mathcal{C})} \text{Hom}_{\mathcal{C}}(x, y_i)$$

which is all the morphisms in \mathcal{C} that from x to others. For any $f, g \in \text{Ob}(x \backslash \mathcal{C})$, $f : x \rightarrow y_1$, $g : x \rightarrow y_2$ for some $y_1, y_2 \in \text{Ob}(\mathcal{C})$, then the morphism in $x \backslash \mathcal{C}$ is defined as the composition

$$\text{Hom}_{x \backslash \mathcal{C}}(f, g) := \text{Hom}_{\mathcal{C}}(y_1, y_2)$$

which means the morphisms $\gamma : f \rightarrow g$ are the morphisms $\gamma : y_1 \rightarrow y_2$ such that $\gamma(f) := \gamma \circ f = g$ makes the diagram below commutes

$$\begin{array}{ccc} & x & \\ f \swarrow & & \searrow g \\ y_1 & \xrightarrow{\gamma \in \text{Hom}_{x \backslash \mathcal{C}}(f, g)} & y_2 \\ & \gamma \in \text{Hom}_{\mathcal{C}}(y_1, y_2) & \end{array}$$

The motivation of defining this is that we want to generalize our covering idea to fundamental group or groupoid, as you can see both of them can be considered as categorical objects, so the covering should be a functor.

Definition 5.4 (*Covering of Groupoids*) Let \mathcal{B} and \mathcal{C} be two small connected category, meaning the objects form a set not a proper class, and any two object have at least one invertible morphism between them. Then the covering between \mathcal{B} and \mathcal{C} is a surjective functor $p : \mathcal{B} \longrightarrow \mathcal{C}$ such that

$$p : \text{Ob}(b \backslash \mathcal{B}) \longrightarrow \text{Ob}(p(b) \backslash \mathcal{C})$$

is a bijection $\forall b \in \mathcal{B}$. Similar to the covering of topological space, for a $c \in \mathcal{C}$, the fiber of c is the set $F_c = \{b \in \mathcal{B} | p(b) = c\}$ and $\forall c \in \mathcal{C}$ we have

$$p^{-1}(\text{Ob}(c \backslash \mathcal{C})) = \bigsqcup_{b_i \in F_c} \text{Ob}(b_i \backslash \mathcal{B})$$

The objects in $x \backslash \mathcal{C}$ is a set of morphisms of \mathcal{C} with source x we denote it as $\text{St}_{\mathcal{C}}(x)$, so the covering restricts to the bijection $p : \text{St}_{\mathcal{B}}(b) \longrightarrow \text{St}_{\mathcal{C}}(p(b))$ and $p^{-1}(\text{St}_{\mathcal{C}}(c)) = \bigsqcup_{b_i \in F_c} \text{St}_{\mathcal{B}}(b_i)$.

The definition of covering of groupoids is strictly followed by the covering of topological space, with the based point x_0 changed to the morphism with source x_0 . We have the statement below naturally.

Proposition 5.2 The induced functor $\prod(p) : \prod(\hat{X}) \longrightarrow \prod(X)$ is a covering of groupoid if $p : \hat{X} \longrightarrow X$ is a covering of topological space.

Proof This is actually the same statement of **Theorem 5.1** and **Corollary 5.1** as long as consider any path is a invertible morphism in the groupoid as a category. \square

The key of algebraic topology is to use algebraic structure to study and verify difference topological space, and our main work is also trying to discover any potential example to build a bridge between difference mathematical field. We will see how covering space and Galois theory connected to each other by the underlying group of topological space through covering space. Now we will study more on the algebraic side of covering space.

Definition 5.5 (*Automorphism group of groupoid*) Let \mathcal{C} be any groupoid, the automorphism of $x \in \mathcal{C}$ are all the objects in $x \backslash \mathcal{C}$ which from x sends to x itself and denoted as $\pi(\mathcal{C}, x)$, in mathematical words

$$\pi(\mathcal{C}, x) := \text{Hom}_{\mathcal{C}}(x, x)$$

It is obvious that if the \mathcal{C} is any fundamental groupoid of a topological space then the automorphism group is actually the fundamental group with respect to the chosen x_0 , that is

$$\pi(\prod(X), x_0) = \text{Hom}_{\prod(X)}(x_0, x_0) = \pi_1(X, x_0)$$

So for any covering space $p : \hat{X} \longrightarrow X$ we have the covering of underlying groupoid with the connected of groups, the covering of groupoid indicate some information on groups.

Proposition 5.3 Let $p : \hat{X} \longrightarrow X$ be a covering of topological space, then the induced morphism $p_* : \pi(\prod(\hat{X}), e_i) \longrightarrow \pi(\prod(X), x_0)$ is a monomorphism, where $x_0 \in X$ is the based point and $e_i \in F_{x_0} = \{e_i\}_{i \in I}$. Moreover, $\forall e_j, e_k \in F_{x_0}$, $p_*(\pi(\prod(\hat{X}), e_j))$ is conjugate to $p_*(\pi(\prod(\hat{X}), e_k))$ in $\pi(\prod(X), x_0)$.

Proof The injectivity is trivial by the bijection of $\prod(p)$ on $\text{St}(e_i)$. $\prod(\hat{X})$ is a groupoid so there is a path $g : e_j \longrightarrow e_k$, the conjugation is given by the $p(g) \in \pi(\prod(X), x_0)$, that is

$$p_*(\pi(\prod(\hat{X}), e_k)) = [p_*(g)] \circ [p_*(\pi(\prod(\hat{X}), e_j))] \circ [p_*(g)]^{-1}$$

\square

The proposition is saying the underlying group of based space at x_0 is hidden in any copy of group at $e_i \in F_{x_0}$, when the covering space covers to X by p , all the group structure on F_{x_0} will onto the one group at x_0 .

Proposition 5.4 *The group $p_*(\pi(\prod(\hat{X}), e_j))$ runs through all conjugates of $p_*(\pi(\prod(\hat{X}), e_i)) \in \pi(\prod(X), x_0)$ as e_j runs through F_{x_0} .*

Proof This is trivial that the surjectivity of the groupoid covering functor $\prod(p)$ on $\text{St}(e_i)$ and apply the same method in **Proof 5.3** \square

Now the connection between covering space of topological space and groupoid, together with the underlying fundamental group is very clear as the commutative diagram shows below, we consider the fundamental group of a space as the automorphism group under the groupoid category at specific object, all our work is trying to build a categorical eyesight of algebraic topology.

$$\begin{array}{ccccccc}
\hat{X} & \xrightarrow{\quad \Pi \quad} & \prod(\hat{X}) & \xrightarrow{\quad \pi(\mathcal{C}, x) \quad} & \pi(\prod(\hat{X}), e_i) & \xlongequal{\quad} & \pi_1(\hat{X}, e_i) \\
\downarrow p & & \downarrow \prod(p) & & \downarrow p_* & & \downarrow p^* \\
X & \xrightarrow{\text{underlying groupoid}} & \prod(X) & \xrightarrow{\text{automorphism group}} & \pi(\prod(X), x_0) & \xlongequal{\quad} & \pi_1(X, x_0)
\end{array}$$

It is clear that the fundamental group of covering space should have a same corresponding relation as groupoid, if we consider the group as the automorphism of the groupoid category under the covering, then there should be some algebraic relation between fundamental groups.

5.2 Covering space and Galois theory

Galois theory is one of the most powerful algebraic theory. Consider the quadratic equation $ax^2 + bx + c = 0$, we say $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ is the formula of solution, namely the radical. For any higher n degree polynomial equation $\sum_{i=0}^n a_i x^i = 0$, the radical to this equation is a family of functions $x_i = f_i(a_0, a_1, \dots, a_n)$ which satisfies the equations, where any functions only required the operations of $+$, $-$, \times , \div , $\sqrt{\quad}$. The biggest contribution of Galois Theory is the proof of the non-existence of the radical for any equations more than degree 5. In this chapter we will introduce some basic technique of Galois theory and see how it is connected to covering space.

The genius idea of Galois is to connect every equations to its symmetric group. More precisely, every equations's splitting field has a Galois groups and the existence of radical is related to the Galois group is solvable or not.

Definition 5.6 (Ring and Field) *A ring R is a set with binary operation $+$ and \times where $(R, +)$ is a commutative group and \times is associative and distributive over addition. A field F is a ring such that $(F \setminus \{0\}, \times)$ is a commutative group.*

The definition is not new to us, we have a classical field chain that $\mathbb{O} \supset \mathbb{H} \supset \mathbb{C} \supset \mathbb{R} \supset \mathbb{Q} \supset \mathbb{F}_p$ where \mathbb{O} is the Octonions field and \mathbb{H} is the Quaternions field, and \mathbb{F}_p is the finite field or Galois field.
